Steer Axles for Forklifts

Forklift Steer Axle - The classification of an axle is a central shaft meant for turning a wheel or a gear. Where wheeled vehicles are concerned, the axle itself could be attached to the wheels and rotate together with them. In this situation, bearings or bushings are provided at the mounting points where the axle is supported. Conversely, the axle can be fixed to its surroundings and the wheels can in turn revolve around the axle. In this particular case, a bearing or bushing is located within the hole within the wheel to be able to allow the wheel or gear to turn around the axle.

When referring to trucks and cars, several references to the word axle co-occur in casual usage. Usually, the word refers to the shaft itself, a transverse pair of wheels or its housing. The shaft itself revolves together with the wheel. It is frequently bolted in fixed relation to it and called an 'axle shaft' or an 'axle.' It is equally true that the housing surrounding it that is usually called a casting is otherwise called an 'axle' or sometimes an 'axle housing.' An even broader sense of the term means every transverse pair of wheels, whether they are attached to one another or they are not. Hence, even transverse pairs of wheels in an independent suspension are often known as 'an axle.'

In a wheeled motor vehicle, axles are an essential part. With a live-axle suspension system, the axles function to be able to transmit driving torque to the wheel. The axles even maintain the position of the wheels relative to one another and to the vehicle body. In this system the axles must likewise be able to support the weight of the motor vehicle along with whatever cargo. In a non-driving axle, like the front beam axle in several two-wheel drive light vans and trucks and in heavy-duty trucks, there would be no shaft. The axle in this particular condition serves just as a steering part and as suspension. Lots of front wheel drive cars consist of a solid rear beam axle.

There are various kinds of suspension systems wherein the axles work just to transmit driving torque to the wheels. The angle and position of the wheel hubs is a function of the suspension system. This is often seen in the independent suspension seen in nearly all brand new SUV's, on the front of several light trucks and on the majority of new cars. These systems still consist of a differential but it does not have fixed axle housing tubes. It could be attached to the motor vehicle frame or body or even could be integral in a transaxle. The axle shafts then transmit driving torque to the wheels. The shafts in an independent suspension system are like a full floating axle system as in they do not support the vehicle weight.

To finish, with regards to a motor vehicle, 'axle,' has a more vague description. It means parallel wheels on opposing sides of the motor vehicle, regardless of their mechanical connection kind to one another and the vehicle body or frame.
